Leipzig, SS 2011

- levels or organization
 - **Primary structure:** sequence of amino acids (from N- to C-terminus)
 - **Secondary structure:** β -sheets and α -helices
 - **Ternary structure:** arrangement of secondary structure elements into folds
 - **Quaternary structure:** assoziation of polypeptide chains into one protein
- proteins can be unfolded and refolded
- conformation is assumed to be the thermodynamically preferred one
- mathematical models should allow to predict protein structure from the protein sequence
- → **Molecular Modelling**

Anfinsen's dogma and Levinthal's paradox

Anfinsen's dogma

- The native structure of a protein is determined only by the protein's amino acid sequence.
- The native structure is a **unique, stable** and **kinetically accessible** minimum of the free energy.

Levinthal's paradox

- The number of possible **conformations available** to a given protein is **astronomically large**.
- A polypeptide chain of 100 residues will have 99 peptide bonds, and therefore 198 different phi and psi bond angles. If each of these bond angles can be in one of three stable conformations, the protein may fold into a maximum of 3^{198} different conformations.

Folding Funnel

Primary Structure

A polypeptide is a single linear **polymer chain** of **amino acids** bonded together by **peptide bonds** between the carboxyl and amino groups of adjacent amino acid residues.

During the condensation reaction a water molecule is released per formed peptide bond.

Polypeptide chain characteristics

The peptide bond is **planar** due to its **double bond character**.

II

Loren Williams, Georgia Tech

Polypeptide chain characteristics

| bond angle | dihedral/torsion angles | | |
|------------------------------|---|---|--|
| | $N - C_\alpha$ ϕ (<i>phi</i>) | $C_\alpha - C_1$ ψ (<i>psi</i>) | $C_1 - N$ ω (<i>omega</i>) |
| <i>cis</i> | | | 0° |
| <i>trans</i> | | | 180° |
| right-handed α -helix | -57° | -47° | |
| antiparallel β -sheet | -139° | $+135^\circ$ | |
| parallel β -sheet | -119° | $+113^\circ$ | |

Possible combinations of ϕ and ψ values are visualized in **Ramachandran plots** (see next slides).

Secondary Structure Elements I

Parallel and anti-parallel β -strands can form β -sheets.

Secondary Structure Elements II

Hydrogen bonds between every N-H group and the oxygen of a C=O group four amino acids down the chain hold the α -helices in shape.

- atoms are point charges with an associated mass
- collective mathematical expression is the potential function
- subsumes energetic contributions from multiple physical forces
- and between (all) pairs of atoms (“pair potential”)
- represented as force field
- **molecular mechanics** minimizes the (static) potential energy
- **molecular dynamics** models the behaviour of the system over time

Forces that determine protein structure

- bonded energy contribution
 - bond lengths
 - bond angles
 - torsion angles
- non-bonded energy contribution
 - van der Waals forces
 - electrostatic interactions
- conjugated system distortion
- hydrogen bonds
- solvent

$$E^{total} = E^{bond} + E^{angle} + E^{torsion} + E^{Waals} + E^{coulomb}$$

Bond length, angle and torsion

Penalty for molecule geometry deviating from optimal.

$$E_{ij}^{bond} = \frac{1}{2} k_{ij}^{bond} (r_{ij} - r_{ij}^0)^2 \quad (1)$$

$$E_{ijk}^{angle} = \frac{1}{2} k_{ijk}^{angle} (\theta_{ijk} - \theta_{ijk}^0)^2 \quad (2)$$

$$E_{ijkl}^{torsion} = \frac{1}{2} V_n (1 + \cos n\phi_{ijkl}) \quad (3)$$

r_{ij}^0 ... optimal bond length
 θ_{ijk}^0 ... optimal valence angle
 V_n ... height of the torsional barrier
 ϕ_{ijkl} ... torsional angle
 k ... constants

van der Waals forces

The **Lennard-Jones potential** is a simple model to approximate the interaction between a pair of **neutral** atoms.

$$E_{ij}^{\text{vanderWaals}} = \frac{A_{ij}}{r_{ij}^{12}} - \frac{B_{ij}}{r_{ij}^6} \quad (4)$$

Coulomb's law describes the electrostatic interaction between **electrically charged** atoms. The dipole interactions of amide groups along the protein backbone has a significant influence on the overall conformation.

$$E_{ij}^{coulomb} = \frac{1}{k_{ij}^{coul}} \frac{q_i q_j}{r_{ij}} \quad (5)$$

r_{ij} ... distance between atoms i and j
 q_i, q_j ... partial charges on atoms i and j
 k_{ij}^{coul} ... constant

Assisted Model Building with Energy Refinement (AMBER) – represents a functional form of force fields as well as a molecular dynamics software package.

$$E^{total} = \sum E_{ij}^{bond} + \sum E_{ijk}^{angle} + \sum E_{ijkl}^{torsion} + \sum E_{ij}^{vanderWaals} + \sum E_{ij}^{coulomb}$$

Energy terms for Hydrogen bonds

$$E_{ij}^{hydro} = \frac{C_{ij}}{r_{ij}^{12}} - \frac{D_{ij}}{r_{ij}^{10}} \quad (6)$$

The equation takes only the distance of i (H on H-Donor) and j (O on H-Acceptor) into account but not the angle.

Biophysical Chemistry, Part I: The conformation of biological macromolecules by Charles R. Cantor and Paul R. Schimmel; W. H. Freeman and Company, 12. edition, 2002; Chapter 5: “Conformational analysis and forces that determine protein structure”, p252-309.
