Basic Model Assumptions

- DNA region consisting of $N = 60$ nucleosomes isolated by boundary elements
- three kinds of nucleosomes exist:
 - unmodified (U)
 - methylated or modified (M)
 - acetylated or anti-modified (A)
- nucleosomes are actively interconverted by recruited (de-)modifications enzymes
Enzymes are recruited by a selected nucleosome.
- nucleosomes are randomly interconverted in a recruitment-independent manner
- the rates of the interconversion reactions are the same for all nucleosomes

Basic Ingredients of the Model

Implementation

step 1 Selection of a random nucleosome n_1 to be modified

a specific n_1 is selected with probability $1/N$ (here: $N = 60$)
with probability α a recruited conversion will be attempted
with probability $(1 - \alpha)$ a random conversion will be attempted

step 2A recruited conversion

standard version: a second random nucleosome n_2 is selected **from anywhere** and is changed “one-step towards n_2 ”

n_1	A	A	A	U	U	U	M	M	M
n_2	A	U	M	A	U	M	A	U	M
new n_1	A	U	U	A	U	M	U	U	M

step 2B random conversion or noisy conversion

nucleosome n_1 is changed “one-step towards” either of the other types with probability $1/3$

n_1	A	A	A	U	U	U	M	M	M
new n_1	A	U	M	A	U	M	A	U	M
probability	$1/3$	$2/3$	0	$1/3$	$1/3$	$1/3$	0	$2/3$	$1/3$

feedback-to-noise ratio

$$F = \frac{\alpha}{(1 - \alpha)} \text{ for } \alpha \in [0, 1]$$

more feedback-dependent conversions than noisy conversions
if $F > 1$

“gap” measure

$$G = \frac{1}{t} \sum_{i=1}^t \frac{|M - A|}{|M + A|}$$

measures the size of the “gap” between the peaks in the
probability distribution

Bistability Is a Function of Noise

M ... number of nucleosomes in the M state at timepoint t

$P(M)$... probability to observe M nucleosomes in state M over time δt

When feedback is only twice as strong as noise ($F = 2.0$) –

Bistability Is a Function of Noise

The left panels of A-D are samples of the time development of the number M of nucleosomes in state M. The right panels of A-D show the corresponding probability distribution of M obtained from long simulations.

Figure E measures the lifetime of the high-M or high-A state, while the system is said to be in the high-M state when $M > 1.5A$ and in the high-A state when $A > 1.5M$.

Figure F: relationship between the feedback-to-noise ratio and the average “gap” between the numbers of M and A nucleosomes at any time point.

Run the simulation yourself!

What is the Origin of Cooperativity in the Model?

- Bistability not only requires positive feedback but also nonlinearity in the feedback loop. This is usually achieved by cooperativity.
- There is no **explicit** cooperativity in the model.

Hypothesis

The model is implicitly cooperative with respect to the conversion from A to M (and *vice versa*) since the transition require an M ($n_2 = M$) for the deacetylation $A \rightarrow U$ and an M ($n_2 = M$) for the methylation $U \rightarrow M$. The conversion thus has a rate proportional to M^2 .

Eliminating Bistability

- remove the recruited modification reactions ($U \rightarrow A$, $U \rightarrow M$) \Rightarrow no cooperativity, no bistability
- remove the recruited **de**-modification reactions ($A \rightarrow U$, $M \rightarrow U$) \Rightarrow no cooperativity, no bistability

Restoring Bistability

introduce explicit cooperativity by introducing dependence on two nucleosomes n_2 and n_3 into the remaining recruited reactions.

recruited conversion

- **cooperative modification version:**

if $n_2 = n_3 = M$, then $n_1 = U$ is changed to $n_1 = M$ and
if $n_2 = n_3 = A$, then $n_1 = U$ is changed to $n_1 = A$.

- **cooperative de-modification version:**

if $n_2 = n_3 = U$, then n_1 is changed to $n_1 = U$ and
if $n_2 = n_3 = A$, then $n_1 = M$ is changed to $n_1 = U$ and
if $n_2 = n_3 = M$, then $n_1 = A$ is changed to $n_1 = U$.

Conversions in the Single-Feedback Models

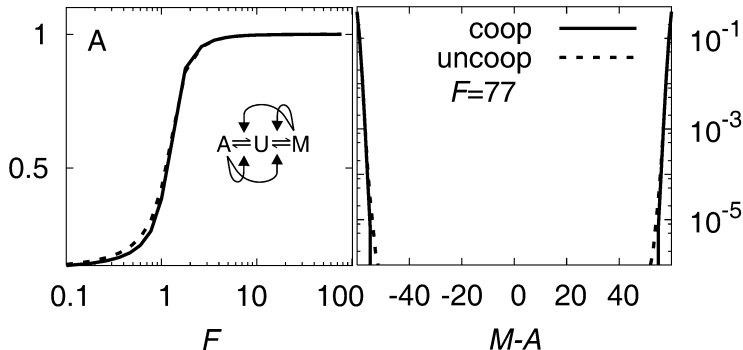

The instruction specified under **cooperative modification** (coop. mod. vers.) and **cooperative de-modification** (coop. demod. vers.) specify variants to the standard version of step 2A in the implementation.

n_1	A	A	A	U	U	U	M	M	M	
n_2	A	U	M	A	U	M	A	U	M	
standard version	A	U	U	A	U	M	U	U	M	Fig A
coop. mod. vers.	A	A	A	A	U	M	M	M	M	Fig B
coop. demod. vers.	A	U	U	U	U	U	U	U	M	Fig C

See Figures A,B and C on the following pages.

Implicit Cooperation – Fig A

standard version

Adding additional cooperativity to the standard version of the model has little effect on the bistability. (Compare the solid and dashed lines.)

Explicit or No Cooperation – Fig B

cooperative modification version

Strong bistability is achieved by cooperation in the modification reaction as depicted here.

cooperative demodification version

Weak bistability is achieved by cooperation in the de-modification reaction as depicted here.

A Need for “Beyond-Neighbor” Interactions

Consider where n_2 nucleosomes come from that are involved in recruitment of enzymes to n_1 .

- **Standard model:** All nucleosomes in the region have the same capability to stimulate enzyme recruitment to n_1 .
- **Neighbor-limited model:** Only the two nearest neighbors of n_1 have the capability to stimulate enzyme recruitment to n_1 .
- **Power-law contact model:** The capability of stimulating enzyme recruitment to n_1 depends on the distance of n_2 and n_1 . The probability of contact is proportional to $\frac{1}{d^{1.5}}$ and therefore power-law distributed.

Standard Model

Curves for different F -values (1, 2.6, 6, 26, 77) are given in the right panels.

At nearly all time points nucleosomes are either in all-M or all-A state for $F = 2.6$.

Neighbor-limited Model

Bistability is difficult to achieve. Even a large majority of nucleosomes with one kind of modification is unable to prevent the random growth of patches of nucleosomes carrying the competing modification.

Power-law Contact Model

The existence of a low rate of long-range contacts is all that is necessary to allow robust stability of both states (here at $F = 7$).

Heritability of Nucleosome Modifications
